The Unity Trainer ensures that everything is working fine - have a look at the trainer.Northwestern University researchers have found that a drug used to treat malaria, amodiaquine, is actually able to increase the risk of severe brain damage in young children, even when they were not exposed to malaria. The research is published in the July 2 online issue of the New England Journal of Medicine. The study involved 63 hospitals in Niger, Malawi, Nigeria and Uganda. Researchers analyzed records of 1,174 children who were treated for malaria in pregnancy. Of the children who had amodiaquine, a teratogen, they looked at the effect of the drug on those who were considered not to have been exposed to malaria. Of those who were not exposed to malaria, 22 percent of the children who had received amodiaguine had a sign of cerebral palsy. In contrast, the figure was just 7 percent of the children who had not received amodiaquine. Children with the highest levels of fetal exposure to amodiaquine were

most likely to develop cerebral palsy. The authors, who are based at the National Institutes of Health, plan to conduct a similar study in the United States. "This study shows, for the first time, that a drug routinely used to treat malaria actually increases the risk of brain damage in children, even when children are not exposed to malaria," says Joseph Murray, MD, Ph.D., author of the article and professor of pediatrics and preventive medicine at Northwestern University Feinberg School of Medicine, "We also find that those children are more likely to have other, less easily remedied problems, such as other forms of brain damage." The researchers also found that amodiaguine may be an even more potent risk factor for severe brain damage in children who were exposed to malaria. This was true for both those who were exposed to high levels of the drug and those who were not. Amodiaquine is a synthetic chloroquine derivative. In 2006, the World Health Organization expanded its list of essential medicines and included amodiaquine for treating malaria. The drug is safe and widely used in the developing world, where it is typically used as a single dose during pregnancy to prevent and treat malaria in children. Murray emphasizes that this study focused only on children born in Africa. However, it is not yet known what the long-term effects of the medication will be in children born in the United States.
