Tmpgenc Authoring Works 5 Keygen Download .Fishing is a popular hobby in the United States and abroad. However, the sport is inherently dangerous. A lost, swallowed or tangled fishing lure or hook is a constant hazard to the fishermen's health and safety. While, tackle makers offer numerous fishing lures and hooks which are intended to be easily attached to the fishing line, there is no known reliable, easily used apparatus which has been devised to find lost or mislaid fishing hooks. The need is solved with the present invention. Endeavour, the spacecraft that successfully launched aboard the space shuttle Challenger on April 6th, 1986 and landed a month later, will end its career in the ocean off the coast of California in a little over 12 hours. On January 28th, the orbiter will rendezvous with the jet-powered deep-diving vehicle Endeavour II, a vessel operated by the National Oceanic and Atmospheric Administration (NOAA), and cause the spacecraft to sink to its home in the ocean. When Endeavour is lost into the Pacific, it will join its sister orbiter, Columbia, which fell into the ocean in 2003. The Columbia was recovered about five months later, repaired, and continues to fly to the International Space Station today. Endeavour's recovery also would involve extensive repair work, and the loss of the shuttle's robotic arm, which would have been required to hoist the vehicle out of the water. Two ocean recovery vessels, USS Kearsarge and USS Halifax, had been assigned to recover Endeavour after its retirement. However, on Monday morning, Endeavour's flight director, Bill Gerstenmaier, told reporters that Endeavour had not properly appeared in the navigation log of the Kearsarge, so the vessel was ordered to stay in port until the shuttle falls into the ocean. Neither Endeavour nor the ocean recovery vehicle Endeavour II is equipped to survive in the deep ocean. Only a recovery vessel can extract them. The hole in the shuttle's wing will be patched first, and then Endeavour and Endeavour II will be towed to the deck of the transport vessel Ronald H. Brown. In turn, the two orbiters will be placed on an underwater recovery frame called a plow, at which point Endeavour II will be lowered into the ocean, and Endeavour will be raised out of the water. The entire process is expected to take about four hours. End
